Covid-19 (2019-nCoV) Antigen Rapid Test Cassette

Performance Evaluation Report

DEWEI MEDICAL started to research and develop Covid-19 (2019-nCoV) Antigen Rapid Test Cassette from 2020, and finished 3 batches of trial products in Jul, 2020. According to the guidelines of 《2019 review of new coronavirus antigen / antibody detected tests technology》 and EN13612: 2002, we evaluated the product performance and made the following summary:

1. Intended use

The product is used for the qualitative detection of SARS-COV-2 infection. The entire detection process takes only 15-20 minutes, and the operation is simple and sensitive. No instrument required. It can be used for the screening of early infected patients and asymptomatic patients. This method is an effective supplement for nucleic acid detection.

2. Diagnostic principles

The detection of SARS-COV-2 adopts the principle of double antibody sandwich method and colloidal gold immunochromatography to qualitatively detect SARS-COV-2 antigen in human nasal swabs, oral swabs, pharyngeal swabs, sputum, bronchoalveolar lavage fluid, etc., with two highly specific and highly sensitive SARS-COV-2 N antigen monoclonal antibodies, wherein monoclonal antibody I is a capture antibody, fixed in the detection area on the NC membrane, monoclonal antibody II is a colloidal gold-labeled antibody, sprayed on the binding pad, and the NC membrane quality control area C is coated with goat anti-mouse IgG antibody and goat anti-rabbit IgG antibody . The double antibody sandwich method is used in the detection area, and the antigen-antibody reaction is used in the quality control area, combined with colloidal gold immunochromatography technology to detect the SARS-COV-2 in the human body. During detection, the sample is chromatographed under the capillary effect. If the tested sample contains SARS-COV-2, the gold-labeled SARS-COV-2 N antigen monoclonal antibody I combines with SARS-COV-2 to form a complex, and combines with the a SARS-COV-2 N antigen monoclonal antibody II fixed at the detection line during the chromatography process, which will form the "Au-antibody I-N antigen- antibody II" sandwich, so that a purple band appears in the detection area (T); Otherwise, no magenta bands appear in the detection area (T). Regardless of whether there is a SARS-COV-2 antigen in the sample, the complex will continue to be chromatographed up to the control area (C), and a purple band appears when reacting with the goat anti-mouse IgG antibody and goat anti-rabbit IgG antibody.

The purple-red band presented in the control area (C) is a standard for judging whether the chromatographic process is normal, and also serves as an internal control standard for reagents.
